# CH 40 – LOG AND EXPONENTIAL EQUATIONS

---

---

## □ INTRODUCTION

**D**o you recall the formula  $A = A_0 e^{kt}$  for exponential growth and decay from Chapter 37? We used it to solve various problems where we wanted to determine either the final amount,  $A$ , or the initial amount,  $A_0$ , of whatever quantity is changing. But what if we wanted to find the time it takes for something to happen; that is, what if we're looking for  $t$ ? Based on the algebra we've learned so far in this course, there's no way to isolate the  $t$ . We now remedy that issue.

First and foremost: Don't forget the definition of **log**:

$$\log_b x = y \text{ means } b^y = x$$

## □ SOLVING LOG EQUATIONS

EXAMPLE 1: Solve for  $x$ :  $\log_8 x - 2 = 0$

Solution:

$$\begin{aligned} \log_8 x - 2 &= 0 && \text{(the original equation)} \\ \Rightarrow \log_8 x &= 2 && \text{(first step to isolate the } x) \\ \Rightarrow 8^2 &= x && \text{(change to exponential form)} \\ \Rightarrow \boxed{x = 64} &&& \text{(calculate the value of } x) \end{aligned}$$

Quick Check:  $\log_8 64$  is 2, and 2 minus 2 equals 0. ✓

**EXAMPLE 2:** Solve for  $y$ :  $\log(3y + 5) = 1$

**Solution:** Note: This is the common log, base 10.

$$\begin{aligned} \log(3y + 5) &= 1 && \text{(the original equation)} \\ \Rightarrow 10^1 &= 3y + 5 && \text{(change to exponential form)} \\ \Rightarrow 3y + 5 &= 10 && \text{(rearrange and simplify)} \\ \Rightarrow 3y &= 5 && \text{(subtract 5 from each side)} \\ \Rightarrow \boxed{y = \frac{5}{3}} &&& \text{(divide each side by 3)} \end{aligned}$$

**EXAMPLE 3:** Solve for  $x$ :  $\ln(7 - 4x) = \frac{1}{2}$

**Solution:**  $\ln$  is just another log, and its base is understood to be  $e$ .

$$\begin{aligned} \ln(7 - 4x) &= \frac{1}{2} && \text{(the original equation)} \\ \Rightarrow e^{1/2} &= 7 - 4x && \text{(convert to exponent form)} \\ \Rightarrow 4x &= 7 - \sqrt{e} && \text{(move the } -4x \text{ and the } e^{1/2}, \text{ and} \\ &&& \text{write the power of } e \text{ in radical} \\ &&& \text{form)} \\ \Rightarrow x &= \frac{7 - \sqrt{e}}{4} && \text{(divide each side by 4)} \end{aligned}$$

So the exact solution is

$$\boxed{x = \frac{7 - \sqrt{e}}{4}}$$

We can use a calculator to approximate the solution as 1.338.

---

## Homework

---

1. Solve each log equation:

a.  $\log_6 x = 2$

b.  $\log_5 x = 3$

c.  $\log_2 x = \frac{1}{2}$

d.  $\log_3 x = -4$

e.  $\log_7(x+2) = 1$

f.  $\log(2x-1) = 2$

g.  $\ln x = 3$

h.  $\ln(x-1) = 1$

i.  $\ln(3x-5) = 0$

j.  $\ln(2x+5) = \frac{1}{4}$

### □ **THE POWER PROPERTY OF LOGS**

To motivate this section, please consider trying to solve the exponential equation

$$3^x = 5$$

Could  $x = 1$ ? No.  $3^1 = 3$ , too small.

Could  $x = 2$ ? Also No.  $3^2 = 9$ , too big.

Since  $3^1 = 3$  and  $3^2 = 9$ , it appears that  $x$  should be somewhere between 1 and 2; let's try  $x = 1.5$ . We'll calculate  $3^{1.5}$  in two ways, just for practice:

$$3^{1.5} = 3^{1\frac{1}{2}} = 3^{3/2} = \sqrt{3^3} = \sqrt{27} = 3\sqrt{3}, \text{ which is clearly not } 5.$$

And using a calculator,  $3^{1.5} \approx 5.19615$ , kind of close to 5, but certainly not close enough to claim we have a solution. We could keep guessing for a really long time — and we could even figure out a “solution” to any degree of accuracy we would want — but trust me: We would never get the exact answer by guessing. We need a new tool that will allow us to get a hold of that darned  $x$  up in the exponent. It's called the **Power Property of Logs**.

# 4

We know that  $\log_{10} 1,000 = 3$  (since  $10^3 = 1,000$ ). Now watch this:

$$\begin{aligned} & \log_{10} 1,000 \\ = & \log_{10} 10^3 && \text{(since } 10^3 = 1,000\text{)} \\ = & 3 \cdot \log_{10} 10 && \text{[just for giggles, bring the 3 down in front]} \\ = & 3 \cdot 1 && \text{(}\log_{10} 10 = 1\text{, since } 10^1 = 10\text{)} \\ = & 3 && \text{(do you really need a reason here?)} \end{aligned}$$

the same answer!

What did we do here? We took the exponent, the 3, and moved it down in front of the word *log*, making it a coefficient (3 times the log). Seems a bit tricky, but it worked. In fact, this always works:

$$\log_b x^n = n \log_b x$$

The Power  
Property of  
Logs

## □ SOLVING EXPONENTIAL EQUATIONS USING LOGS

EXAMPLE 4: Solve for  $x$ :  $3^x = 5$

Solution: The variable is in the exponent. This is a dilemma. How do we get the unknown out of the exponent so that we can solve for it?

The Power Property of Logs comes to the rescue:

$$\log_b a^x = x \log_b a$$

It allows us to move the exponent to the front (making it a coefficient), but only if we're taking the log of an expression. So the procedure here will be to take a log (we'll choose  $\ln$ , since it's

on your calculator and  $\ln$  is used in calculus), bring down the exponent, and then solve for it.

$$\begin{aligned}
 3^x &= 5 && \text{(the original equation)} \\
 \Rightarrow \ln 3^x &= \ln 5 && \text{(take the } \ln \text{ of both sides)} \\
 \Rightarrow x \ln 3 &= \ln 5 && \text{(the Power Property of Logs)} \\
 \Rightarrow x &= \frac{\ln 5}{\ln 3} && \text{(simple algebra – solve for } x\text{)} \\
 \Rightarrow x &= \frac{1.609437912}{1.098612289} && \text{(use your calculator)} \\
 \Rightarrow &\boxed{x = 1.464973521} && 
 \end{aligned}$$

Note that the exact answer,  $x = \frac{\ln 5}{\ln 3}$ , is an irrational number, while the answer in the box is a rational approximation of the exact answer, but is quite good enough for applications in business and science.

**EXAMPLE 5:** Solve for  $n$ :  $2^{3n+2} = 7$

Solution:

$$\begin{aligned}
 2^{3n+2} &= 7 && \text{(the given equation)} \\
 \Rightarrow \ln 2^{3n+2} &= \ln 7 && \text{(take the } \ln \text{ of each side)} \\
 \Rightarrow (3n+2) \ln 2 &= \ln 7 && \text{(the Power Property of Logs)} \\
 & \text{[Notice the parentheses around the } 3n+2\text{]} \\
 \Rightarrow 3n(\ln 2) + 2\ln 2 &= \ln 7 && \text{(distribute)} \\
 \Rightarrow (3\ln 2) n &= \ln 7 - 2\ln 2 && \text{(subtract the constant } 2\ln 2\text{)} \\
 \Rightarrow n &= \frac{\ln 7 - 2\ln 2}{3\ln 2} && \text{(divide each side by } 3\ln 2 \text{ to} \\
 &&& \text{get the } \underline{\text{exact}} \text{ answer)}
 \end{aligned}$$

$$\Rightarrow \boxed{n = 0.269118307} \quad \text{(use your calculator to get a rational approximation)}$$

**EXAMPLE 6:** Solve for  $a$ :  $5^{2a-3} = 6^{a+1}$

Solution:

$$\begin{aligned} 5^{2a-3} &= 6^{a+1} && \text{(the original equation)} \\ \Rightarrow \ln 5^{2a-3} &= \ln 6^{a+1} && \text{(take the } \ln \text{ of each side)} \\ \Rightarrow (2a-3)\ln 5 &= (a+1)\ln 6 && \text{(Power Property of Logs)} \\ \Rightarrow 2a\ln 5 - 3\ln 5 &= a\ln 6 + \ln 6 && \text{(distribute)} \\ \Rightarrow 2a\ln 5 - a\ln 6 &= \ln 6 + 3\ln 5 && \text{(variables to the left and constants to the right)} \\ \Rightarrow a(2\ln 5 - \ln 6) &= \ln 6 + 3\ln 5 && \text{(factor out the variable)} \\ \Rightarrow \boxed{a = \frac{\ln 6 + 3\ln 5}{2\ln 5 - \ln 6}} &&& \text{(divide to isolate the } a) \end{aligned}$$

This is the exact answer. A rational approximation would be  $a = 4.638776$ .

---

## Homework

---

Solve each equation and round your answers to the nearest ten thousandths place:

$$\begin{array}{lll} 2. & 2^x = 72 & 3. & 5^{-y} = 3 & 4. & 3^{4n-1} = 5 \\ 5. & 3^{z+1} = 8^{3-z} & 6. & 3^{5c} = 7^{10c} & 7. & e^{3x+4} = 25 \\ 8. & 3^{-n} = 43 & 9. & 7^{4-3x} = 2 & 10. & e^x = 2^{x-6} \end{array}$$

## □ THE GROWTH AND DECAY FORMULA REVISITED

The growth and decay formula

$$A = A_0 e^{kt}$$

worked just fine back in Chapter 37 when we were searching for either the starting (initial) amount  $A_0$  or the ending (final) amount  $A$ . But when the unknown was in the exponent, we were stuck. Now we're not stuck.

**EXAMPLE 7:** Assuming an initial population of 7500 elephants, a final population of 12,000, and a time period of 7 years, find the annual growth rate.

**Solution:** We will write the growth formula, substitute the given values, and then solve for the unknown  $k$ :

$$\begin{aligned}
 A &= A_0 e^{kt} && \text{(the growth formula)} \\
 \Rightarrow 12,000 &= 7500 e^{k \cdot 7} && \text{(substitute the given values)} \\
 \Rightarrow e^{7k} &= \frac{12,000}{7500} && \text{(isolate the } e^{7k} \text{)} \\
 \Rightarrow e^{7k} &= 1.6 && \text{(calculator)} \\
 \Rightarrow \ln e^{7k} &= \ln 1.6 && \text{(take the } \ln \text{ of each side)} \\
 \Rightarrow 7k \ln e &= \ln 1.6 && \text{(Power Property of Logs)} \\
 \Rightarrow 7k &= \ln 1.6 && (\ln e = 1) \\
 \Rightarrow k &= \frac{\ln 1.6}{7} && \text{(solve for } k \text{)} \\
 \Rightarrow k &= 0.067 && \text{(calculator gives a decimal)}
 \end{aligned}$$

And therefore the annual growth rate is 6.7%

**EXAMPLE 8:** How long will it take for an investment of \$10,000 to reach a final amount of \$32,000 if the interest rate is 7.3% per year compounded continuously?

**Solution:** The phrase “compounded continuously” justifies the use of our growth formula.

$$\begin{aligned}
 A &= A_0 e^{kt} && \text{(the growth formula)} \\
 \Rightarrow 32,000 &= 10,000 e^{0.073t} && \text{(remember: } 7.3\% = .073\text{)} \\
 \Rightarrow e^{0.073t} &= \frac{32,000}{10,000} && \text{(divide each side by 10,000)} \\
 \Rightarrow e^{0.073t} &= 3.2 && \text{(arithmetic)} \\
 \Rightarrow \ln e^{0.073t} &= \ln 3.2 && \text{(take the } \ln \text{ of each side)} \\
 \Rightarrow 0.073t &= \ln 3.2 && \text{(Power Property of logs and } \ln e = 1\text{)} \\
 \Rightarrow t &= \frac{\ln 3.2}{0.073} = 15.933 && \text{(solve for } t\text{)}
 \end{aligned}$$

Thus, the amount of time it will take to reach the goal is

15.933 years
--------------

**EXAMPLE 9:** The decay rate of a radioactive substance is 12%/year, compounded continuously. How long will it take for 40 grams of the substance to decay, leaving 10 grams?

**Solution:**  $A = A_0 e^{kt}$  (the growth formula)

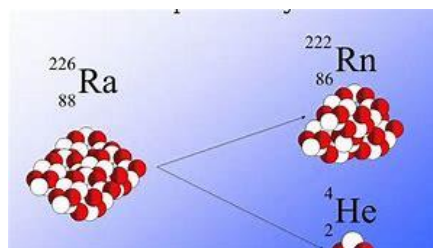

In this problem, the starting amount is 40 g, the ending amount is 10 g, and the decay rate,  $k$ , is negative 0.12.

$$\begin{aligned} \Rightarrow 10 &= 40e^{-0.12t} && \text{(note: } k < 0) \\ \Rightarrow 0.25 &= e^{-0.12t} && \text{(divide each side by 40)} \\ \Rightarrow \ln 0.25 &= \ln e^{-0.12t} && \text{(take the } \ln \text{ of each side)} \\ \Rightarrow \ln 0.25 &= -0.12t \ln e && \text{(Power Property of Logs)} \\ \Rightarrow -1.386294 &= -0.12t && (\ln e = 1) \\ \Rightarrow t &= \frac{-1.386294}{-0.12} \\ \Rightarrow &\boxed{11.6 \text{ years}} \end{aligned}$$

## Homework

11. In the growth formula  $A = A_0 e^{kt}$ , solve for
  - a.  $A_0$
  - b.  $k$
  - c.  $t$
12. Find the interest rate if an investment of \$7200 reached a total of \$18,000 in 5 years.

13. If the population is growing 9% per year, how long will it take for a population of 25,600 to reach a population of 100,000?
14. Find the annual growth rate if a population increased from 2000 to 7500 in a period of 9 years.
15. \$25,000 is invested in a money market account paying 9.5% per year compounded continuously. How many years will it take for that investment to reach a total of \$75,000?
16. The decay rate of a radioactive substance is 7%/year, compounded continuously. How long will it take for 88 kg of the substance to decay, leaving 41 kg?
17. Assuming an initial amount of 25 g of a radioactive substance, and assuming continuous radioactive decay, what is the decay rate if there are 7 g remaining after 12 years?

---

## Solutions

---

1. a. 36      b. 125      c.  $\sqrt{2}$       d.  $\frac{1}{81}$       e. 5  
 f.  $\frac{101}{2}$       g.  $e^3$       h.  $e + 1$       i. 2      j.  $\frac{\sqrt[4]{e} - 5}{2}$
2. 6.1699      3. -0.6826

$$4. \quad 3^{4n-1} = 5 \Rightarrow \ln(3^{4n-1}) = \ln 5 \Rightarrow (4n-1)\ln 3 = \ln 5$$

$$\Rightarrow n = \frac{\frac{\ln 5}{\ln 3} + 1}{4} \approx .6162$$

$$5. \quad 1.6173$$

$$6. \quad 3^{5c} = 7^{10c} \Rightarrow \ln(3^{5c}) = \ln(7^{10c}) \Rightarrow 5c \ln 3 = 10c \ln 7$$

$$\Rightarrow 5c \ln 3 - 10c \ln 7 = 0 \Rightarrow c(5 \ln 3 - 10 \ln 7) = 0$$

$$\Rightarrow c = \frac{0}{5 \ln 3 - 10 \ln 7} \Rightarrow c = 0$$

$$7. \quad -0.2604$$

$$8. \quad -3.4236$$

$$9. \quad 1.2146$$

$$10. \quad -13.5533$$

$$11. \text{ a. } A_0 = \frac{A}{e^{kt}}$$

$$\text{ b. } A = A_0 e^{kt} \Rightarrow \frac{A}{A_0} = e^{kt} \Rightarrow \ln \frac{A}{A_0} = \ln e^{kt}$$

$$\Rightarrow \ln A - \ln A_0 = kt \Rightarrow k = \frac{\ln A - \ln A_0}{t}$$

$$\text{ c. } t = \frac{\ln A - \ln A_0}{k}$$

$$12. \quad 18\%$$

$$13. \quad 15 \text{ yrs}$$

$$14. \quad 14.7\%$$

$$15. \quad 11.56 \text{ yrs}$$

$$16. \quad 10.91 \text{ yrs}$$

$$17. \quad 10.6\%$$
